

Scenario 1: Infrequently, when the river is high and flowing into the forest, and the water will stay on the floodplain for long enough, we will open the regulators and leave the water to flow naturally.

Scenario 2: Often, when the river is high and flowing into the forest, but the flood won't last as long as it's needed, we will shut the regulators and hold the water on the floodplain, before returning the water to the river.

Scenario 3: If the floodplain is too dry, we can use a temporary pump to get environmental water onto the floodplain and close the regulators to hold the water there for as long as needed, before returning the water to the river.
